

ABSTRACT OF THE INVENTION

A syringe guide for a syringe and vial is disclosed. The syringe guide serves as a guide for the needle to be inserted into the vial. The syringe guide can be made in different sizes, with different materials, and using different constructive ways. It consists of a pipe having a large diameter at one end and a small diameter at the opposite end. The vial and syringe are placed in the syringe guide according to their relative diameters. The diameter of the syringe guide can increase due to the slit running the entire length. A wall inside the syringe guide where the small and large diameters of the pipe meet supports the vial. When withdrawing medication while both the vial and syringe are in the guide, one does not have to hold the vial. The syringe guide makes working with a needle, cleaner, and easier.
